Abstract: Automatic program verification, proving program correct still requires substantial expert manual effort. One of the biggest burden is providing loop invariants properties that hold for every iteration of a loop. Compared to other requirement elements such as pre-and post conditions, loop invariants tend to be difficult to understand and to express. The proposed system automates the functional verification of incomplete correctness of programs with loops by inferring the required loop invariants. In this approach it combines complementary techniques such as test case generation, dynamic invariant detection, and static verification. This approach can be implemented by a tool called DYNAMATE. DYNAMATE improves the flexibility of loop invariant inference by combining static (proving) and dynamic (testing) techniques. The DYNAMATE tool presented in this process combines different techniques with the overall goal of providing fully automatic verification of programs with loops.

Keywords – Loop Invariants, Mutation testing, Full functional , Dynamic analysis, Static checking, Dynamate

I. INTRODUCTION

Every large software system has a small set of functions on whose correctness it depends. To prove that such function conform to their specification, automated proves require loop invariants properties that hold for every iteration of loop. Dynamte infers loop invariants by systematically mutating post conditions dynamic checking based on automatically generated tests weed out invalid candidates and retains the valid invariants. Dynamate paves the way for fully automatic verification. The current Dynamate prototype integrates the EvoSuite test case generator, the Daikon invariant detector and the ESC/Java2 static verifier as well as our implementation of the gin-pink techniques to dynamically detect loop invariants based on syntactically mutation post condition.

Verifiers that can confirm programs correct against their full functional specification require, for programs with loops extra annotations in the form of loop invariants. For programs with loops, one of the biggest burdens is providing loop invariants property that hold for every iteration of a loop. Compared to pre- and post conditions, it is much more difficult to write loop invariants. In this approach evolution automation of full program verification through loop invariants [1]. This approach is based on included of static (program proving) and dynamic(testing) techniques. The current DynaMate prototype combine the EvoSuite test case generator, the Daikon invariant detector and the ESC/Java2 static verifier. Fully automatic verifiers such as cccheck or BLAST fail to establish the correctness of the annotated program., auto-active verifiers such as ESC/Java2 succeed.

In Exiting system Verifiers that can confirm programs correct against their full functional specification require programs with loops Programs with loops, one of the main burdens is providing loop invariants properties that hold for every iteration of a loop. this mainly drawback Loop invariants should be complicated to analyze. The proposed system automates the functional
verification of partial truth of programs with loops by inferring the required loop invariants. In this approach it combines complementary techniques such as test case generation, dynamic invariant detection, and static verification. This approach can be implement by a tool called DYNAMATE, a fully automatic verifier for Java programs with loops. DYNAMATE improves the flexibility of loop invariant inference by integrate static (proving) and dynamic (testing) techniques. This advantage of identifying loop invariants program with easy analysis. Dynamate is best performance with other tool.

1.1 Evo suite
This new approach in the EVOSUITE tool, and compared it to the common approach of addressing one goal at a time. Evaluated on open source libraries, EVOSUITE implements the approach presented in generating JUnit test suites for Java code. EVOSUITE works on the byte-code level and collect all necessary information for the test cluster from the byte-code via Java indication. During test generation, EVOSUITE considers one top level class at a time. The class and all its unnamed and member classes are instrumented at byte-code level to keep track of called methods and branch distances during execution. To produce test cases as compilable JUnit source code, EVOSUITE accesses only the public interfaces for test generation; any subclasses are also careful part of the unit under test to allow testing of abstract classes. To execute the tests throughout the search, EVOSUITE uses Java Reflection.

This technique to automate test generation, shown that optimizing whole test suites toward a coverage criterion is superior to the traditional approach of targeting one coverage goal at a time. In our experiments, this results in significantly better overall coverage with smaller test suites.

1.1.2 Diakon
Daikon is an execution of dynamic detection of likely invariants; that is, the Daikon invariant detector reports likely program invariants. An invariant is a asset that holds at a certain point or points in a program; these are often seen in declare statements, documentation, and formal specifications. Dynamic invariant detection runs a program, observes the values that the program computes, and then information properties that were true over the observed executions. Daikon can detect property in C, C++, C#, Eiffel, F#, Java, Perl, and Visual Basic programs.

This section gives gradually instructions for installing Daikon. Here is an summary of the steps. Details appear below:
Select the instructions for your operating system.
1. Download Daikon.
2. Place three commands in your shell initialization file.
3. Optionally, modify your installation.
4. Optionally, compile Daikon and construct other tools.

Requirements for running Daikon
In order to run Daikon, you must have a Java 7 (or later) JVM (Java Virtual Machine). You must also have a Java 7 (or later) compiler.

- [Figure 1: Daikon’s Infrastructure]
Daikon proposes to automatically determine program invariants and report them in a meaningful manner. Detect invariants from program executions by instrumenting the source program to trace the variables of interest, running the instrumented program over a set of test cases, and inferring invariants over both the instrumented variables and derived variables that are not manifest in the original program.

1.1.3 ESC/java2
ESC/Java2 is a tool for static verification program specifications. It expands significantly upon ESC/Java, on which it is built. It is reliable with the definition of JML and of Java 1.4. It adds additional static checking to that in ESC/Java; most considerably, it adds support for checking frame conditions and annotations containing method calls. This document describes the position of the final release of ESC/Java2, along with some notes regarding the details of that implementation JML should be easy to use for any Java programmer JML assertions are added as comments in .java file, between /*@ . . . @*/, or after //@, Properties are specified as Java boolean expressions, extended with a few operators (old, forall, result, . . . ), using a a small number of keywords (requires, ensures, signals, assignable, pure, invariant, non null, . . . ).

The goal of the ESC/Java2 work is to expand the use of ESC/Java by a. updating the parser of ESC/Java so that it is consistent with the present definition of JML and Java, b. packaging the updated tool so that it is more easily available to a big set of users, consistent with the source code license provisions of the ESC/Java source code, c. and extending the choice of JML annotations that can be checked by the tool, where possible and where consistent with the engineering goals of ESC/Java. the status of their implementation in ESC/Java2, the degree to which the annotation is logically checked, and any differences between ESC/Java2 and JML.

ESC/Java2 is a tool for statically checking program specifications. It expands significantly upon ESC/java, on which it is built. It is consistent with the definition of JML and of Java 1.4. It adds additional static checking to that in ESC/Java; most significantly, it adds support for checking frame conditions and annotations containing method calls. This document describes the status of the final release of ESC/Java2, along with some notes regarding the details of that implementation.

1.2 Overview of The Dynamate
DYNAMATE inputs a program M and its specification—a precondition P and a post condition Q. Two outcomes of the algorithm are possible: achievement means that DYNAMATE has found a set of valid loop invariants that are sufficient to statically verify M beside its specification (P,Q); failure means that DYNAMATE cannot find new valid loop invariants, and those found are insufficient for static verification. DYNAMATE’s main loop starts by executing the test case generator, which produces a new set T of test cases that implement M with inputs satisfying the precondition P. The loop feeds on the whole set TS of test cases generated so far to the dynamic invariant detector, which outputs a set of candidate loop invariants I. To find out which candidates are indeed valid, DYNAMATE calls the static verifier on the program annotated with all candidates I the verifier income a set of proved candidates J (a subset of I), which DYNAMATE adds to the set Inv of established loop invariants. Then, using the current Inv, it calls the static verifier again, this time trying to produce a proof of M against (P,Q). If verification succeeds, DYNAMATE terminates with success a static verifier that is sound but incomplete, unproved candidates in Inv are not necessarily invalid.

Algorithm: dynamate
Require: program M, precondition p, postcondition q, TS (set of test case) INV (set of verified loop invariants)

@IJRTER-2016, All Rights Reserved 62
C (set of candidate) 
While static verification can’t prove (M,P,Q,INV) 
T ← execute test case generator on (M,TS) 
If I has not changed then 
Return (“failure”,IVN) 
End if 
M’ ← annotate M with candidate invariants I 
J ← statically check valid invariants of (M’,P) 
INV ← INV ∩ J 
C ← INV 
End while 
Return (“success”,INV) 

1.2.1 Running Example: Binary Search 
binarySearch0, a helper method declared in class java.util.Arrays in the standard Java

```java
/*
 * @requires a != null;
 * @requires TArrays.within(a, fromIndex, toIndex);
 * @requires TArrays.sorted(a, fromIndex, toIndex);
 * @requires \result \geq 0 \implies a[\result] = key;
 * @requires \result \leq 0 \implies :TArrays.has(a, fromIndex, toIndex, key);
 * @*/
private static int binarySearch0(int[] a, int fromIndex, int toIndex, int key) {
    int low = fromIndex, high = toIndex - 1;
    while (low <= high) {
        int mid = (low + high) >>> 1;
        int midVal = a[mid];
        if (midVal < key) low = mid + 1;
        else if (midVal > key) high = mid - 1;
        else return mid; // key found
    }
    return -(low + 1); // key not found
}
```

Figure 2: Binary search method in java.util.Arrays annotated with pre- and postcondition.

Figure 3: Loop invariants required for verifying method binarySearch0.

JML [2], using model-based predicates [3], representing implicit quantified expressions, with descriptive names. For example, the condition :TArrays. has(a, fromIndex, toIndex, key) means that array a has no element key over the interval range from fromIndex (included) to toIndex (excluded).
II. RELATED WORK

DYNAMATE is center this section on the problem of inferring loop invariants to automate functional verification

2.1 Integrating Daikon and ESC/java

Dynamic detection propose likely invariants based on program executions, but the resulting properties are not guaranteed to be true of over all possible executions Static verification checks that properties are always true, but it can be difficult and dull to select a goal and to annotate programs for input to a static checker. Combining these techniques overcomes the weakness of each, how to integrate two complementary techniques for manipulating program invariants: dynamic invariants detection and static verification[74 ] Static verification of dynamically detected program invariants: Integrating Daikon and ESC/Java

2.2 Identifying loop invariants

Identifying for invariants using genetic programming and mutation testing[80] As most programs are not annotated with invariants, before research has attempted to automatically produce them from source code In this new approach to invariant generation using search, reuse the test generation front-end of existing tool Daikon and integrate it with genetic programming and a mutation testing tool There are two exceptional problems to be solved: firstly, to reduce the number of uninteresting invariants produced and secondly, to show the search to invariants that may be interesting but deceptive" to the search

2.3 verification java program

Proof of Java programs using symbolic execution and invariant generation[9] Software verification is recognized as an impart and complicated problem Presented a novel framework based on symbolic execution, for the verification of software This framework explanation in the from of technique specification and loop invariants. Our framework is built on top of the java path finder form checking toolset and it was used for the verification several non-trivial java program

2.4 static techniques

Combination of static techniques. HAVOC using a static verifier to check if candidate assertions are valid: it creates an early set of candidates (possibly including loop invariants) by applying a fixed set of rules to the available component-level contract (i.e. component, invariants and interface specifications). Like DYNAMATE, HAVOC[12] applies the HOUDINI algorithm to establish which candidates are valid. Using only static techniques.

2.5 Dynamic Techniques

The GUESS-AND-CHECK [13] algorithm infers invariants in the form of algebraic equalities (polynomials up to a given degree) The GUESS-AND-CHECK algorithm proceeds iteratively in two phases The “guess” phase uses linear algebra techniques to competently derive a candidate invariant from data. This candidate invariant is subsequently validated in a “check” phase dynamical discovery invariants instrumental techniques While the overall structure of GUESS-AND CHECK has some similarities to ours, DYNAMATE targets general-purpose programs, which requires very different techniques. The work on DAIKON [7].

2.6 Hybrid Techniques

CEGAR techniques has combined static verification and test case generation. The SYNERGY algorithm [14]. The DASH algorithm builds on SYNERGY to handle programs with pointers without whole-program may-alias analysis Two broad approaches to property checking are testing and verification Testing works best when errors are easy to find, but it is often difficult to get sufficient coverage for correct programs verification methods are most successful when proofs are easy to find, but they are often incompetent at discovering errors.
III. HOW DYNAMATE WORK

The DYNAMATE tool present with combines different techniques with the overall goal of providing fully automatic verification of programs with loops. The only required input to DYNAMATE is a Java program(method) annotated with a JML functional specification (pre- and post condition). DYNAMATE will try to construct a correctness proof of the program with respect to the specification; to this end it will infer necessary loop invariants. Even in the cases where it fails to find all required loop invariants, DYNAMATE still may find some useful invariants and use them to discard some proof obligations, thus providing partial verification.

Advantages of DYNAMATE. The integration of techniques and tools in DYNAMATE compensates for individual shortcomings and achieves a greater whole in terms of flexibility and degree of automation. Dynamic techniques are capable of conclusively invalidating large amounts of loop invariant candidates, thus winnowing a smaller set of candidate invariants that hold in all executions, and can test candidates in isolation (dependencies are not an issue). This leaves the static verifier with a more manageable task in terms of number of candidates to check at once. The GIN-DYN component is an original contribution of DYNAMATE. Based on the observation that loop invariants can often be seen as weakened forms post conditions [1], GIN-DYN derives loop invariant candidates by mutating post conditions. This enables inferring loop invariants that are not limited to predefined templates but stem from the annotated Java program under analysis. DYNAMATE still avails of the advantages of static techniques in terms of soundness: the static verification module scrutinizes the output of the dynamic parts until it can verify it (and uses verified invariants to construct a correctness proof).

The program code is first fed into a test case generator, which generates executions covering official behavior. From these, two dynamic invariant detector tools mine possible loop invariants, based both on fixed patterns (DAIKON)[7] as well as post conditions (GIN-DYN)[5] The candidates are not invalidated by the generated runs and then fed into a symbolic program verifier. The verifier then may create a program proof (bottom right), but may also disprove candidates, which initiates another round of executions, and thus developed invariants.

![Figure 4: Dynamate work](image)

If the verifier fails to verify the program correct, a round of four steps begins

**Step 1: test cases:** To carry dynamic invariant detection, a test case generator construct executions of the program that satisfy the given precondition.
Step 2: candidate invariants. From the resulting executions, an invariant detector animatedly mines candidates for loop invariants.

Step 3: invariant verification. The existing set of loop invariant candidates are fed into a static program verifier.

Step 4: program verification and modification. Using the verified invariants, the static verifier may also be competent to produce a proof that the program is accurate with respect to its specification. If the proof does fail using the loop invariants inferred so far, another round generating, mining, and verifying starts.

How DYNAMATE works, using binarySearch0 as running example

3.1 Input: Programs and Specifications
DYNAMATE receives as input a Java method M with its functional specification consisting of precondition P and postcondition Q. Pre- and postcondition are written in JML. P and Q generally consist of a number of clauses, each denoted by the keyword requires (precondition) and ensures (postcondition) . While DYNAMATE can work with JML specifications in any form, to find it efficient to follow the principles of the model-based approach to specification. Following the model-based specification style entails three main advantages for our work. First, it improves the abstraction and clarity of specifications, and hence it also facilitates reuse with dissimilar implementations it should be clear that has(a, fromIndex, toIndex, key) means that array a contain a value key within fromIndex and toIndex.

Second, model-based specifications also make it easy to resolve static and a runtime semantics. When developing predicates in TArrays we defined each predicate as a static boolean method with both a Java implementation and a JML specification

        Fromindex <= I <= toindex^key=a[i];

A third advantage of using model-based specifications is leveraged by the DYNAMATE approach and more precisely by the GIN-DYN invariant detector described.

3.2 Test Case Generation
The DYNAMATE algorithm needs tangible executions to dynamically gather loop invariants. DAIKON mines relations that hold in all passing test cases and GIN-DYN filters out invalid loop invariant candidates that are inaccurate by a test case. While any test case generator could work with DYNAMATE, our prototype integrates EVOSUITE [6], a completely automatic search-based tool using an inherent algorithm. Since EVOSUITE tries to maximize branch coverage, it has a good chance of produce tests that pass all precondition checks and thus represent valid executions according to the specification.

3.3 Dynamic Loop Invariant Inference
The DYNAMATE algorithm lies a component that detects “likely” loop invariants based on the actual executions provided by the test case generator. The present DYNAMATE implementation in two modules with balancing functionalities. DAIKON’s and GIN-DYN’s invariants are complementary; for example, neither one suffices for a correctness proof of binarySearch0. DAIKON invariants are usually an essential basis to establish GIN-DYN.

How DYNAMATE uses GIN-DYN and DAIKON.
Dynamic invariants detection with DAISON
DAIKON [7] is a broadly used dynamic invariant detector which supports a set of basic invariant templates. Given a test suite and a set of program locations as input, DAIKON instantiates its templates with program variables, and traces their values at the locations in each and every one executions of the tests.
Since DYNAMATE needs loop invariants, it instructs DAIKON to draw variables at four different location of each loop: before loop entry, at loop entry, at loop exit, and after loop exit.

| TABLE 1 loop invariant candidates produced by DAIKON in the first iteration of DYNAMATE. |
|---------------------------------|---------------------------------|-----------------|
| ID    | CANDIDATE                                                                 | VALID |
| c1    | key \in \{-1000, 0\}                                                     | NO    |
| c2    | a \neq null                                                              | YES   |
| c3    | a[i]'s elements one of \{-915, 0\}                                       | NO    |
| c4    | Arrays.INSERTION_THRESHOLD \neq toIndex                                   | NO    |
| c5    | low \geq fromIndex                                                       | YES   |
| c6    | low \geq key                                                              | NO    |
| c7    | high < toIndex                                                           | YES   |
| c8    | high > key                                                                | NO    |
| c9    | high \leq a.length -1                                                     | YES   |
| c10   | toIndex > fromIndex                                                      | NO    |

GIN-DYN: Invariants from Postconditions
GIN-DYN: a way to efficiently generate a large amount of invalid or uninteresting invariant candidates how GINDYN does the filtering, again based on a mixture of dynamic and static techniques. The relax of the current section briefly discusses how invariant candidates formed by GIN-DYN are used within DYNAMATE. In truth, GIN-DYN produces the two fundamental invariants on lines in Figure 4 necessary for a truth proof of binarySearch0. The final set of verified loop invariants includes those of with 28 more, consisting of 13 invariants establish by DAIKON and 20 invariants found by GIN-DYN.

3.3 Static Program Verification
The DYNAMATE algorithm complement dynamic analysis with a static program verifier, which serves two purposes: (1) verifying loop invariant candidates, and (2) using verified loop invariants to carry out a conclusive truth proof.

proof of Loop Invariants
The DYNAMATE prototype relies on the ESC/Java2 static verifier, which works on Java programs and JML annotations.
DYNAMATE always calls ESC/Java2 with the –loop Safe option enabled.

Program Proof
At the end of each iteration, DYNAMATE uses the present set of valid loop invariants to attempt a correctness proof of the program beside its specification. If ESC/Java2 succeeds, the whole DYNAMATE algorithm stops with success.

Refining the Search for Loop Invariants
Original loop invariant candidates may be over specific and hence unsound— Since this may indicate unknown program behavior, for every such candidate L, DYNAMATE adds the conditional check

3.4 Using Dynamate
Present DYNAMATE in action on the implementation of binary search available in class java.util.Array from java’s JDK
The input to dynamate consists of method binarySearch0 Annotated with JML specification Figure.3 when it starts, Dynamate open an HTML report which show the program and specification
whith all elements (statements or annotations) that trigger an ESC/java2 warning highlighted in Yellow. Clicking on a highlighted elements display its currents status, including ESC/java2’s warning message. After each iteration of its main loop (Figure 4), Dynamate Updates the reports elements for which all Associated ESC/java2 warnings have been discharged are highlighted in green. In addition, users can inspect the generated loop invariants by clicking on any loop header. By default only verified loop invariants are shown (in green). Candidate invariants can be viewed (in yellow) by de-selecting a check-box. These candidates have not been falsified by test, nor have they been verified by ESC/java2.

Figure 5 shows a report after the first iteration on binarySearch0: DYNAMATE has proven several simple scalar invariants for the selected loop.

Figure 5: DYNAMATE’s report after iteration #1 on binarySearch0.

Verified statements and annotations (first and last highlighted element) are shown in green, unverified ones in yellow. Loop headers are highlighted in light blue. The right frame shows the proven loop invariants for the selected loop.

IV. SUMMARY OF CONTRIBUTION

The main analysis of this paper are:
1) DYNAMATE: an algorithm to automatically discharge proof obligations for programs with loops, based on a grouping of dynamic and static techniques.
2) GIN-DYN: an automatic technique to increase the dynamic detection of loop invariants, based on the idea of syntactically mutating post conditions [8].
3) This implementation of the DYNAMATE algorithm that integrates the EVOSUITE test case generator, the DAIKON dynamic invariant detector, and the ESC/Java2 static verifier, as well as GIN-DYN.
4) An evaluation of our DYNAMATE prototype on a case study linking 28 methods with loops from java.util classes.
5) A comparison against state-of-the-art tools for automatic verification based on predicate abstract

V. CONCLUSION AND FUTURE WORK

This problem overcomes three techniques and used test case generated, dynamic invariants detection, and static verification this three techniques as development our prototype Dynamate automatically discharged 97 percent of all proof obligations for 28 methods with loops from java.util classes.
Our future work will focus on the following issues:

**Better test generators.** As any module in DYNAMATE can be replaced by a better implementation of the same functionalities, currently investigating dynamic-symbolic approaches to test case generation [16] as well as hybrid techniques integrating search-based and symbolic approaches [17].

**More diverse invariant generators**
This technique based on symbolic execution such as the one implemented in DYSY [19] to provide for more and more diversified, loop invariant candidates.

**Stronger component integration**
DYNAMATE can become a platform on which several approaches to test generation, dynamic analysis, and static verification can work in synergy[14] to produce a greater whole.

**Availability:** The current prototype of DYNAMATE is available for download at [http://www.st.cs.uni-saarland.de/dynamate-tool/](http://www.st.cs.uni-saarland.de/dynamate-tool/).
